SUMMARY

The life span of C. elegans can be increased via reduced function of the mitochondria; however, the extent to which mitochondrial alteration in a single, distinct tissue may influence aging in the whole organism remains unknown. We addressed this question by asking whether manipulations to ETC function can modulate aging in a cell-non-autonomous fashion. We report that the alteration of mitochondrial function in key tissues is essential for establishing and maintaining a longevity cue. We find that regulators of mitochondrial stress responses are essential and specific genetic requirements for the electron transport chain (ETC) longevity pathway. Strikingly, we find that mitochondrial perturbation in one tissue is perceived and acted upon by the mitochondrial stress response pathway in a distal tissue. These results suggest that mitochondria may establish and perpetuate the rate of aging for the whole organism independent of cell-autonomous functions.

INTRODUCTION

An aging organism exhibits correlated and recognizable changes to its physiology over time. These changes occur coordinately across multiple tissues and organs, in concordance with theories that posit a strong role for the participation of the endocrine system in the regulation of age-related phenotypes (Russell and Kahn, 2007; Tatar et al., 2003). Within invertebrate model organisms such as C. elegans and Drosophila, evidence strongly suggests that tissue-specific manipulations of endocrine pathway components affect the aging process of the entire organism. These include alteration of signals from the somatic germline which control the aging of nonmitotic tissues (Arantes-Oliveira et al., 2002; Hsin and Kenyon, 1999); restoration or reduction of insulin/IGF-1 signaling (IIS) in neuronal or fat tissues (Broughton et al., 2005; Hwangbo et al., 2004; Kapahi et al., 2004; Libina et al., 2003; Wolkow et al., 2000); and genetic manipulations to specific neurons which then alter the capacity for the entire animal to respond to dietary restriction (Bishop and Guarente, 2007). These systems have offered the simplicity of studying tissue-specific expression in organisms in which single-gene mutations can affect longevity, and have been extended to mammalian model systems (Blüher et al., 2003; Conboy et al., 2005; Taguchi et al., 2007). Such evidence indicates that there are key tissues that transmit longevity signals to modulate the aging process. Moreover, these adaptations may have evolved to provide the animal with a mechanism by which an environmental, extrinsic signal could be sensed and then amplified across the entire animal to coordinate the appropriate onset of reproduction, senescence and/or aging.

Life span can be increased by reduced function of the mitochondria. Mutation or reduced function in nuclear genes encoding electron transport chain (ETC) components in yeast, C. elegans, Drosophila, and mice delay the aging process (Cope land et al., 2009; Dell’Agnello et al., 2007; Dillin et al., 2002b; Feng et al., 2001; Hansen et al., 2008; Kirchman et al., 1999; Lapointe et al., 2009; Lee et al., 2002; Liu et al., 2005). In C. elegans, mitochondria undergo a period of dramatic proliferation during the L3/L4 stage (Tsang and Lamire, 2002). After this larval molt is completed, mitochondrial DNA proliferation in post-mitotic tissues is minimal (Tsang and Lamire, 2002). Intriguingly, the L3/L4 larval developmental period has proven to be a critical period in which the ETC modulates the aging process (Dillin et al., 2002b). Thus, the sensing and monitoring of key events during the L3/L4 transition by the ETC longevity pathway initiates and maintains the rate of aging of the animal for the rest of its life. Reduction of the ETC longevity pathway during adulthood can not result in increased longevity, even as ATP synthesis becomes impaired (Dillin et al., 2002a; Rea et al., 2007). How the mitochondrial signaling pathway modulates the aging process and the identity of the pathway constituents that transmit these longevity signals remain unknown.

One possible suggestion for the observation of increased longevity under conditions of reduced mitochondrial function originates from the “rate of living” theory of aging, in existence for over a hundred years, which suggests that the metabolic expenditures of an organism ultimately determine its life span.
(Pearl, 1928; Rubner, 1908). A modification to this theory has suggested alternatively that, because reactive oxygen species (ROS) are generated as a byproduct of the metabolic activity of the mitochondrial ETC during the production of ATP (Harman, 1956), a decrease in ROS production is the major contributing factor to the long-lived phenotypes of ETC mutants (Feng et al., 2001; Rea and Johnson, 2003). Recent evidence (Copeland et al., 2009; Gems and Doonan, 2008; Van Raamsdonk and Hekimi, 2008; Yang et al., 2007) does not support a linear relationship between ROS production and life span. With the increased skepticism toward the oxidative stress theory of aging comes the question: if not by manipulation of ROS in a cell-autonomous manner, then by what mechanism does reduction of mitochondrial function affect aging?

We attempted to address this question by asking whether manipulations to ETC function could modulate aging in a cell-non-autonomous fashion in the nematode C. elegans. We asked whether key tissues could govern increases in longevity when components of the mitochondrial ETC are inactivated. We also reasoned that if we could identify the crucial tissues from which the ETC longevity pathway functions, we could identify the origin of the longevity signal and perhaps potential mediators of this signal.

RESULTS

cco-1 Functions in Specific Tissues to Affect the Aging Process

To ascertain whether tissue-specific ETC knockdown could alter the life span of an organism, we created transgenic worms carrying an inverted repeat hairpin (HP) directed toward the nuclear-encoded cytochrome c oxidase-1 subunit Vb/COX4 (cco-1). cco-1 was chosen because knockdown of this gene results in intermediate phenotypes compared to knockdown of the other ETC genes by RNAi, allowing both positive and negative modulation of longevity to be identified (Dillin et al., 2002b; Lee et al., 2002; Rea et al., 2007). Furthermore, cco-1 RNAi does not result in the detrimental phenotypes observed when bacterial feeding RNAi against other components of the ETC is administered undiluted, such as severe developmental delay and lethality (Copeland et al., 2009; Gems and Doonan, 2008; Van Raamsdonk and Hekimi, 2009; Yang et al., 2007).

In worms and plants, RNAi can have a systemic effect due to spreading of the dsRNA molecules. For example, exposure of the intestine to bacterially expressed dsRNA results in the dsRNA entering through the intestinal lumen but eliciting knockdown in other cells, such as the muscle and hypodermis (Jose et al., 2009). To remove the systemic nature of RNAi from our experimental design, we used systemic RNAi deficient (sid-1(qf9)) mutant worms (Figure 1A). sid-1 encodes a transmembrane protein predicted to serve as a channel for dsRNA entry. While defective for systemic RNAi, the sid-1(qf9) mutants are fully functional for cell-autonomous RNAi (Winston et al., 2002). Lines were generated in the sid-1(qf9) mutant background using an inverted repeat of the cco-1 cDNA under the control of well-characterized promoters expressed in neurons (unc-119 and rab-3) (Maduro and Pilgrim, 1995; Nonet et al., 1997), intestine (ges-1) (Aamodt et al., 1991), and body-wall muscle cells (myo-3) (Miller et al., 1986; Okkema et al., 1993).

Knockdown of cco-1 in the intestine using the ges-1 intestine-specific promoter driving a cco-1 hairpin construct significantly increased life span (Figure 1B, representative line of 13, Table S1, available online), whereas the myo-3 muscle-specific promoter driving a cco-1 hairpin in the body-wall muscle either had no effect or even decreased life span (Figure 1C, representative line of 6, Table S1). The rab-3 neuron-specific promoter driving a cco-1 hairpin also increased life span (Figure 1D, representative line of 2, Table S1). Because the life-span extension in the neuronal promoter line was not as great as that observed in intestinal hairpin lines, we tested another neuronal promoter, the pan-neural unc-119 promoter. Consistent with the rab-3 promoter, we observed a moderate increase in life span across multiple unc-119 promoter transgenic lines (Figure 1E, representative line of 8, Table S1). The results of these experiments suggest a primary requirement for ETC knockdown in intestinal and neuronal tissues for increased longevity, albeit the neuronal derived ETC knockdown was consistently less robust compared to the intestinal knockdown.

We tested an alternative method for tissue-specific RNAi to verify our hairpin approach. Tissue-specific RNAi can also be achieved by feeding dsRNA to rde-1 mutant animals in which the wild-type rde-1 gene has been rescued using tissue-specific promoters (Figure 2A) (Qadota et al., 2007). rde-1 encodes an essential component of the RNAi machinery encoding a member of the PIWI/STING/Argonaute family of proteins.

Life-span analyses were performed with rde-1(nes219) mutant animals in which rde-1 was restored by tissue-specific expression of wild-type rde-1 cDNA (Qadota et al., 2007). rde-1 was rescued in transgenic lines under the control of the lin-28 hypodermal promoter, the hth-1 body wall muscle promoter, and the nhx-1 intestine expressing promoter (Qadota et al., 2007). These lines were then tested for their effects on life span when animals were fed cco-1 dsRNA producing bacteria.

As expected, feeding rde-1(nes219) mutant animals cco-1 dsRNA producing bacteria did not extend life span, since these animals fail to perform RNAi due to the lack of rde-1 (Figure 2B and Table S1). Consistent with the cco-1 hairpin approach, knockdown of cco-1 in the intestine, by restoring rde-1 using the intestine-specific nhx-1 promoter and feeding cco-1 dsRNA bacteria significantly increased life span. In fact, intestinal cco-1 dsRNA fed to rde-1(nes219);nhx-1p::rde-1 worms was able to completely recapitulate the life-span extension generated by feeding cco-1 dsRNA to wild-type animals (Figure 2C and Table S1). Furthermore, cco-1 knockdown in the body wall muscle decreased life span (Figure 2D and Table S1), similar to results obtained from the muscle-specific cco-1 RNAi hairpin experiments. Hypodermal knockdown of cco-1 had no significant effect on life span (Figure 2E and Table S1). Consistent with cco-1 feeding RNAi increasing longevity in an insulin/IGF-1 pathway independent manner, we found the life-span extension of intestinal cco-1 RNAi animals to be daf-16 independent (Figure 2F and Table S1).

Because cco-1 knockdown in two distinct tissues increased longevity, we tested whether combination of the intestinal and nervous system cco-1 knockdown could result in an even further
Figure 1. Life-Span Analysis of cco-1 Hairpin Transgenic Animals
(A) Wild-type worms allow import of dsRNA from surrounding tissues, but sid-1(qt59) mutant worm can not import dsRNA and RNAi knockdown is no longer systemic but is maintained locally within the tissue in which the dsRNA is produced (Winston et al., 2002).
(B) Intestine-specific knockdown of cco-1 results in life-span extension. sid-1(qt59)/rol-6 control (black line, mean 18.8 ± 0.7 days), ges-1p::cco-1 hairpin (green line, 23.9 ± 0.8 days, p < .0001).
(C) Body-wall muscle knockdown of cco-1 does not significantly affect life span. sid-1(qt59)/rol-6 control (black line, mean 18.6 ± 0.5 days), myo-3p::cco-1 hairpin (blue line, mean 18.6 ± 0.5 days, p = 0.0574).
(D) Neuronal knockdown of cco-1 extends life span. sid-1(qt59)/rol-6 control (black line, 18.2 ± 0.2 days), rab-3p::cco-1 hairpin (purple line, 21.7 ± 0.5 days, p < .0001).
(E) Neuronal knockdown of cco-1 driven by the unc-119 promoter also extends life span. sid-1(qt59)/rol-6 control (black line, mean 19.8 ± 0.7 days), unc-119p::cco-1 hairpin (red line, mean 23.8 ± 0.8 days, p = .0001). Please see Table S1 for all statistical analyses and also Figure S1 and Movie S1 for additional experiments.

increase in longevity compared to knockdown in each individual tissue. We crossed our long lived rab-3p::cco-1 hairpin (neuronal) lines to the ges-1p::cco-1 hairpin (intestinal) lines and tested the life span of the double transgenic animal. Animals with cco-1 knocked down in the nervous system and the intestine did not live longer than knockdown in either the nervous system or the intestine (Figure 2G and Table S1). To test this via a second method, we used worms in which a gly-19p::sid-1 transgene could specifically restore the capacity for feeding RNAi within the intestine of sid-1 mutant animals. We again found that feeding worms bacteria expressing cco-1 dsRNA did not further extend the life span of our rab-3p::cco-1 hairpin (Figure S1A). Therefore, there does not appear to be synergy among the tissues in which cco-1 knockdown is required to extend longevity. This finding
Figure 2. Life-Span Analysis of Tissue-Specific Complementation of rde-1 with cco-1 Feeding RNAi

(A) Tissues exposed to dsRNA from feeding RNAi initiate knockdown if rde-1 has been rescued in the corresponding tissue. Neighboring tissues are unable to initiate RNAi if rde-1 is absent.

(B) rde-1(ne219) mutants do not respond to cco-1 feeding RNAi. Animals fed bacteria harboring an empty vector (black line, mean 18.0 ± 0.3 days), cco-1 RNAi (red line, mean 16.16 ± 0.4 days, p < 0.0403).

(C) rde-1 rescued in the intestine (VP303) extends life span when fed cco-1 dsRNA producing bacteria. Animals fed vector only bacteria (black line, mean 14.7 ± 0.6 days), cco-1 RNAi (green line, mean 22.0 ± 0.2 days, p < .0001).

(D) rde-1 rescued in the body wall muscle (NR350) decreases life span when fed cco-1 dsRNA bacteria. Animals fed bacteria harboring empty vector (black line, mean 13.5 ± 0.3 days), cco-1 RNAi (blue line, mean 11.8 ± 0.3 days, p < 0.0002).
suggests that the nervous system and the intestinal cells communicate with each other to modulate aging in response to reduced cco-1 function.

**Tissue-specific ETC Knockdown Uncouples Multiple Correlates of Longevity**

Resistance to oxidative stress, UV damage, and heat stress is associated with multiple forms of increased longevity. We tested whether the increased longevity of the tissue-specific cco-1 RNAi animals was due to resistance to any of these stresses. Tissue-specific knockdown of cco-1 did not affect the response of animals to oxidative stress induced by paraquat in a manner correlated with their longevity phenotype (Table S2), consistent with recent results in worms and flies (Copeland et al., 2009; Doonan et al., 2008; Van Raamsdonk and Hekimi, 2009) (Lee et al., 2002). We next tested whether RNA damage correlated with increased longevity. Again, none of the long-lived tissue-specific hairpin lines were more resistant to UV damage than wild-type animals (Table S3). Finally, we tested whether the long-lived tissue-specific cco-1 hairpin lines were more resistant to heat stress than control animals and found that they were not (Table S4). Collectively, the increased longevity of tissue specific cco-1 hairpin animals did not correlate with the known stress resistance phenotypes associated with other pathways that modulate the aging process (Arantes-Oliveira et al., 2002; Larsen et al., 1995; Lee et al., 1999; Lee et al., 2003; McElwee et al., 2004).

RNAi of cco-1 slows development, growth, movement, and reduces fecundity (Dillin et al., 2002b). Through an RNAi dilution approach, many of these side effects could be uncoupled from longevity, an observation that suggested a quantitative model for ETC function upon these life history traits (Rea et al., 2007). We tested whether a qualitative difference among the mitochondrial ETC from different tissues could also explain these observed side effects. We found that many of these traits could be uncoupled from increased longevity conferred by simply reducing mitochondrial function in a particular tissue. For example, long lived animals in which cco-1 was reduced in neuronal cells produced worms of nearly identical length to their control counterparts (Figure S1B), reached adulthood at the similar rates (data not shown) and had similar numbers of progeny (Figure S1C). These results are consistent with ETC reduction in all tissues of Drosophila increased life span and decreased fertility, while knockdown in neurons increased longevity without affecting fertility (Copeland et al., 2009). Additionally, reduction of cco-1 in the intestine or nervous system did not result in slowed movement; however, reduction in the body wall muscles did (Movie S1). Therefore, in addition to the quantitative model proposed by Rea et al. to explain the developmental and behavioral deficits of ETC RNAi, contributions from specific tissues must also play an important role in these life history traits.

**The Mitochondrial Unfolded Protein Response Is Required for ETC-Mediated Longevity**

In response to a mitochondrial perturbation there exists a stress response mechanism that is communicated to the nucleus to increase the expression of mitochondrial associated protein chaperones, such as HSP-6 and HSP-60, referred to as the mitochondria-specific unfolded protein response (UPR<sup>mit</sup>) (Benedetti et al., 2006; Yoneda et al., 2004; Zhao et al., 2002). hsp-6 is the mitochondrial hsp70 heat shock protein family member and hsp-60 is the mitochondrial GroE/hsp60/hsp10 chaperonin family member. The UPR<sup>mit</sup> is activated upon different forms of mitochondrial stress including the misfolding of mitochondria-specific proteins or stoichiometric abnormalities of large multimeric complexes, such as ETC complexes (Yoneda et al., 2004). Disrupting subunits of ETC complexes by either RNAi or mutation activates the mitochondrial stress response (Benedetti et al., 2006; Yoneda et al., 2004). cco-1 RNAi is a potent inducer of hsp-6 and hsp-60 (Yoneda et al., 2004). Intrigued by this discovery, we tested whether the UPR<sup>mit</sup> might play a central and specific role in the increased longevity generated by ETC RNAi.

We tested whether other well-known pathways that regulate the aging process also induced the UPR<sup>mit</sup>. Unlike cco-1 RNAi-treated animals (Figure 3A), animals treated with RNAi toward daf-2, the IIS receptor, or eat-2 mutant animals, a genetic surrogate for diet restriction induced longevity, did not induce the UPR<sup>mit</sup> (Figures 3B and 3C) even though each of these interventions increase longevity. Therefore, induction of the UPR<sup>mit</sup> appears specific to the ETC longevity pathway and not other longevity pathways.

In addition to the UPR<sup>mit</sup>, the unfolded protein response in the endoplasmic reticulum (UPR<sup>ER</sup>) is also induced under conditions of protein misfolding, although confined to the ER (Ron and Walter, 2007). We tested whether mitochondrial reduction resulted in a general upregulation of all protein misfolding pathways by treating hsp-4p::GFP reporter worm strains (Callon et al., 2002) with cco-1 RNAi. HSP-4 is the worm ortholog of the ER chaperone, BiP, which is transcriptionally induced by the UPR<sup>ER</sup>. Unlike the UPR<sup>mit</sup>, cco-1 RNAi did not induce expression of the UPR<sup>ER</sup> (Figure 3D), although ER stress induced by tunicamycin did. Furthermore, cco-1 RNAi did not inhibit the ability of cells to induce the UPR<sup>ER</sup> by treatment with tunicamycin. We also tested if cco-1 RNAi induced a marker of cytosolic protein misfolding by treating animals containing the hsp-16p::GFP reporter strain (Link et al., 1999) with cco-1 RNAi. HSP-16.2 is

(E) *rde-1* rescued in the hypodermis (NR222) has no effect on life span when fed cco-1 dsRNA producing bacteria. Vector only (black line, mean 13.5 ± 0.3 days), cco-1 RNAi (purple line, mean 14.3 ± 0.4 days, p = 0.148).

(F) Life-span extension by cco-1 feeding RNAi in the intestine of *ges-1*:rde-1 rescued animals is independent of *daf-16*. Intestinal rde-1 rescued worms were fed empty vector (black line), mean 16.4 ± 0.6 days, *daf-16* RNAi diluted 50% with empty vector (gold line, mean 16.3 ± 0.4 days) or *daf-16* diluted 50% with cco-1 RNAi (green 19.9 ± 0.5 days, p < 0.0001). Please see Table S1 for all statistical analysis.

(G) Double transgenic animals carrying *rab-3*:cco-1::HP and *ges-1*:cco-1::HP (blue line, mean life span 23.4 ± 0.6 days) did not live longer than either the *rab-3*:cco-1::HP (red line, mean life span 23.2 ± 0.6 days, p = .64) or the *ges-1*:cco-1::HP (green line, mean life span 22.9 ± 0.6 days, p = .75) animals. *sid-1* control (black line, mean life span 19.2 ± 0.5 days).
a small heat shock protein of the hsp20/alpha-B crystallin family and is under transcriptional control of the heat shock response (hSR) regulated by HSF-1. Much like the UPR\textsuperscript{mt}, cco-1 RNAi was unable to induce this reporter associated with cytosolic misfolding (Figure 3E). As positive controls, heat shock could induce the HSR reporter and cco-1 RNAi did not block this response. Thus, it appears that knockdown of cco-1 specifically induces the UPR\textsuperscript{mt}, and not other protein misfolding pathways.

**The UPR\textsuperscript{mt} Is a Potent Transducer of the ETC-Longevity Pathway**

We tested whether the UPR\textsuperscript{mt} is a key component of the ETC longevity pathway since there appeared to be a positive and specific correlation of induction of the UPR\textsuperscript{mt} and ETC mediated longevity. If the UPR\textsuperscript{mt} is indeed a regulator of the ETC longevity pathway, we predicted that loss of the UPR\textsuperscript{mt} would specifically suppress the extended longevity of ETC reduced animals and not other longevity pathways.

The UPR\textsuperscript{mt} consists of a signaling cascade that results in upregulation of nuclear-encoded genes to alleviate the stress sensed in the mitochondria. Perception of misfolding in the mitochondria requires the nuclear localized ubiquitin-like protein UBL-5, which acts as an essential and specific coactivator of the homeodomain transcription factor, DVE-1. Together, UBL-5 and DVE-1 respond to mitochondrial perturbation to increase expression of mitochondrial chaperones, including hsp-60 and hsp-60 (Benedetti et al., 2006). ClpP is the homolog of the E.coli ClpP protease located in the mitochondria that plays a role in generating the mitochondrial derived signal to activate DVE-1/UBL-5 stress responsive genes (Haynes et al., 2007).

We treated long-lived ETC mutant animals with RNAi directed toward the known pathway components of the UPR\textsuperscript{mt} and tested the resulting life span. Because cco-1 RNAi is extremely sensitive to dilution and is not efficiently knocked down in combination with a second RNAi (Figures S2A and S2B), we first chose to examine the requirement for UPR\textsuperscript{mt} genes on several long-lived mitochondrial mutants. RNAi of ubl-5, the dve-1 transcriptional co-regulator, specifically blocked the extended life span of the mitochondrial mutants, isp-1 (aqm150) and clk-1(e2519) (Figure 4A, Figure S2C, and Table S1) compared to the life span of wild-type animals. RNAi of ubl-5 did not suppress the extended life span of long-lived daf-2 or eat-2 mutant animals (Figures 4B and 4C; Table S1). Furthermore, ubl-5 RNAi did not shorten the life span of wild-type animals (Figure 4D and Table S1). Taken together, ubl-5 appears essential and specific for the extended longevity of mitochondrial mutants.

RNAi of dve-1 suppressed the life span of all long-lived animals and shortened the life span of wild-type animals (Figures S2D–S2G). This result is not surprising given the roles of dve-1 in growth and development and the embryonic lethality observed for homozygous dve-1 mutant animals (Burglin and Cassata, 2002; Haynes et al., 2007). Furthermore, RNAi of hsp-6, hsp-60 or cip-1 suppressed longevity in the same manner as dve-1, suggesting that these RNAi treatments were pleiotropic and simply made the animals sick (data not shown). Thus, our results indicate that ubl-5 is specific for the longevity response, possibly by specifying the transcriptional activity of DVE-1, to mitochondrial ETC mediated longevity and dve-1, hsp-6, hsp-60 and cip-1 have more broad roles in development making their specific roles in mitochondrial ETC mediated longevity difficult to discern at this time.

**The Temporal Requirements of the UPR\textsuperscript{mt} and ETC-Mediated Longevity Overlap**

The life-span extension by ETC RNAi has a distinct temporal requirement during the L3/L4 stages of larval development (Dillin et al., 2002b; Rea et al., 2007). Furthermore, markers of the UPR\textsuperscript{mt}, namely hsp-6p::GFP, have their greatest activation late in larval development at the L4 stage when challenged with mitochondrial stress (Yoneda et al., 2004). We verified these findings by following the activation of the UPR\textsuperscript{mt} of animals treated with cco-1 RNAi and tested whether the timing requirement of cco-1 mediated longevity could be uncoupled from the induction of the UPR\textsuperscript{mt}. Worms carrying the hsp-6p::GFP UPR\textsuperscript{mt} reporter were transferred onto bacteria expressing cco-1 dsRNA at every developmental stage from embryo to day 2 of adulthood (Figures 5A–5C). Worms transferred to cco-1 dsRNA at the L1 stage induced hsp-6p::GFP throughout development, and this signal perpetuated itself into adulthood (Figure S3). Worms could induce the UPR\textsuperscript{mt} if transferred to the cco-1 RNAi treatment before the L4 larval stage (Figures 5B and 5C). At the L4 larval stage, worms transferred to bacteria expressing cco-1 dsRNA were unable to induce the hsp-6p::GFP marker (Figures 5B and 5C) and were not long lived (Dillin et al., 2002b; Rea et al., 2007). Thus, inactivation of cco-1 must be instituted before the L3/L4 larval stage to initiate induction of the UPR\textsuperscript{mt}. Inactivation in adulthood does not induce the UPR\textsuperscript{mt} and does not result in increased longevity.

Inactivation of ETC components during larval development is sufficient to confer increased longevity on adult animals even though the knocked-down ETC component can be restored in adulthood (Dillin et al., 2002b; Rea et al., 2007). We tested

**Figure 3. Induction of the UPR\textsuperscript{mt} Is Specific to the ETC Longevity Pathway**

(A) hsp-6p::GFP reporter worms fed empty vector (EV) containing bacteria have low levels of background GFP (i) overlay; (ii) GFP. hsp-6p::GFP reporter worms fed cco-1 RNAi upregulate the UPR\textsuperscript{mt}. Relative fluorescence was quantified using a fluorescence plate reader (iii). (B) dsf-2 RNAi does not induce hsp-6p::GFP (i) overlay; (ii) GFP. hsp-6p::GFP reporter worms were hatched on empty vector, cco-1, or dsf-2 dsRNA expressing bacteria and allowed to grow to day 1 of adult hood. Relative fluorescence was quantified (iii). (C) Dietary restricted eat-2(ad1116) mutant worms do not upregulate hsp-6p::GFP reporter (i) overlay; (ii) GFP. Relative fluorescence was quantified (iii). (D) The UPR\textsuperscript{mt} is not induced by cco-1 RNAi (i) overlay; (ii) GFP. hsp-6p::GFP transgenic reporter worms were fed empty vector containing bacteria or cco-1 dsRNA bacteria. No fluorescence upregulation was detected (iii). Both EV and to a lesser extent cco-1 RNAi fed worms were able to upregulate the UPR\textsuperscript{mt} upon treatment with tunicamycin, (i and ii) which is known induce UPR\textsuperscript{mt}. Relative fluorescence of was quantified (ii). (E) cco-1 RNAi does not induce a marker of cytosolic protein misfolding stress, (i) overlay; (ii) GFP. hsp16.2p::GFP reporter worms were fed EV or cco-1 dsRNA bacteria. No fluorescence upregulation was detected (iii). As positive controls, heat shock for 6 hr at 31°C could induce the heat shock response (HSR) and cco-1 RNAi did not block this response (i and ii). In all panels, error bars indicate standard deviations (SD).
Figure 4. *ubl-5* Is Necessary and Specific for ETC-mediated Longevity

(A) The long life span of *isp-1(qm150)* mutant animals is dependent upon *ubl-5*. *isp-1(qm150)* (empty vector, black line, mean 25.8 ± 1.0 days), *isp-1(qm150)* fed *ubl-5* dsRNA bacteria (orange line, mean 15.5 ± 0.7 days, p < 0.001), N2 wild-type (gray line, mean 19 ± 0.5 days).

(B) *daf-2(e1370)* mutant life span is unaffected by *ubl-5* knockdown. *daf-2(e1370)* mutant animals grown on empty vector bacteria (black line, mean 40.1 ± 1.2 days), *daf-2(e1370)* fed *ubl-5* dsRNA bacteria (orange line, mean 39.9 ± 1.2 days, p = 0.327).

(C) Dietary restricted *eat-2(ad1116)* mutant life span is not dependent on *ubl-5*. N2 on empty vector (gray line, mean life span 18.2 ± 0.4 days); *eat-2(ad1116)* on empty vector (black line, mean 26.4 ± 0.6 days); *eat-2(ad1116)* fed *ubl-5* dsRNA bacteria (orange line, mean 23.3 ± 0.7 days, p < 0.0004).

(D) N2 wild-type life span is unaffected by *ubl-5* knockdown. N2 grown on empty vector bacteria (black line, mean 18.2 ± 0.4 days), N2 fed *ubl-5* dsRNA bacteria (orange line, mean 20.3 ± 0.4 days, p = 0.0834). All statistical data can be found in Table S1. See also Figure S2 for additional experiments.

whether developmental inactivation of *cco-1* could not only induce, but whether it could also maintain activation of the UPR\textsuperscript{mt} during adulthood, even though adult inactivation of *cco-1* was unable to induce the UPR\textsuperscript{mt}. Worms treated with *cco-1* RNAi during larval development and then moved to dicer (dcr-1) RNAi (a key component of the RNAi machinery) to block further RNAi activity on day 1 of adulthood have an extended life span ([Dillin et al., 2002b]). Similarly, *hsp-6p::GFP* worms treated with *cco-1* RNAi during larval development and moved onto *dcr-1* RNAi maintained the induced response of the UPR\textsuperscript{mt} (Figures 5D and 5E). Therefore, inactivation during larval development of *cco-1* is sufficient to initiate and maintain a signal to increase longevity and induce the UPR\textsuperscript{mt} in adult animals. The results of these experiments match the timing requirements of the life-span extension for ETC RNAi-treated worms and support the idea that the signals for increased longevity and induction/maintenance of the UPR\textsuperscript{mt} are not separable.

The UPR\textsuperscript{mt} Responds to Cell-Non-Autonomous Cues from ETC Knockdown

Intrigued by the tissue-specific nature by which *cco-1* depletion can modulate the aging process of the entire animal, the specific role of the UPR\textsuperscript{mt} in the longevity response in ETC mutant animals and the overlapping timing requirements for both ETC RNAi and induction of the UPR\textsuperscript{mt}, we hypothesized that the induction of the UPR\textsuperscript{mt} may be able to act cell-non-autonomously in a multicellular organism. If so, we reasoned that induction of the UPR\textsuperscript{mt} in one tissue by *cco-1* reduction might lead to the UPR\textsuperscript{mt} being upregulated in a distal tissue that has not experienced *cco-1* reduction (Figure 6A). Consistent with this hypothesis, transgenic worms with the *cco-1* hairpin expressed in all neurons (either the *rab-3* or the *unc-119* promoter driven *cco-1* hairpin) were able to induce *hsp-6p::GFP* expression in the intestine (Figure 6B). In fact, neuronal RNAi of *cco-1* induced the UPR\textsuperscript{mt} reporter to the same extent as animals with intestinal *cco-1* RNAi (Figures 6B and 6C). We were unable to ascertain whether mitochondrial ETC knockdown in the intestine could signal to the nervous system to induce the UPR\textsuperscript{mt} due to the low expression of the *hsp-6p::GFP* reporter in neuronal cells.

Because *ubl-5* RNAi could block the long life span of mitochondria mutants and *ubl-5* is required for induction of the UPR\textsuperscript{mt}, we tested whether reduction of *ubl-5* in the intestinal cells could block the induction of the cell-non-autonomous signal for the UPR\textsuperscript{mt} that originated from the nervous system.
Figure 5. The Temporal Activation of ETC-generated Longevity Signal Is Coincident with Induction of the UPR^{mt}

(A) hsp-6p::GFP reporter worms were transferred to cco-1 RNAi at each larval developmental stage and early adulthood. GFP fluorescent measurements were taken 16 hr after reaching young adulthood in all cases.

(B) hsp-6p::GFP is upregulated if transfer occurs before the L4 stage of development.

(C) Quantification of hsp-6p::GFP in (A); error bars represent standard deviation (SD).

(D) cco-1 knockdown during larval development is sufficient to induce the hsp-6p::GFP reporter in adulthood. hsp-6p::GFP reporter worms grown on cco-1 dsRNA bacteria during development and then moved to dcr-1 dsRNA producing bacteria at the L4 larval stage, to disrupt the RNAi machinery allowing CCO-1 levels to return to normal. UPR^{mt} remains induced.

(E) hsp-6p::GFP fluorescence 48 hr after transfer to dcr-1 RNAi as described by schematic D. See also Figure S3.

We created lines expressing the rab-3p::cco-1HP in conjunction with a gly-19p::ubl-5HP containing the hsp-6p::GFP reporter. Surprisingly, we found that ubl-5 reduction in the intestinal cells could not block the induction of the UPR^{mt} from signals generated in the nervous system (Figure 6D). Furthermore, intestine-specific depletion of ubl-5 was not sufficient to block the long life span of animals with reduced cco-1 expression in the nervous system (Figure 6E). However, intestine-specific knockdown of ubl-5 did block induction of the UPR^{mt} in the intestinal cells of animals fed bacteria expressing dsRNA of cco-1 (Figure 6F and Figure S4A). Neuronal cells are not able to induce a RNAi response to feeding dsRNA, indicating that ubl-5 is required for induction of the UPR^{mt} in response to cco-1 reduction in nonneuronal cells, but other, yet to be defined factors,
Figure 6. Cell-Non-Autonomous Upregulation of the UPR<sup>mt</sup>

(A) Representation of cell-autonomous and non-autonomous upregulation of UPR<sup>mt</sup>. “X”s depict tissue where cco-1 is knocked down (intestine or neurons). Green indicates location of upregulation of hsp-6p::GFP reporter (intestine upon knockdown in intestine or neurons).

(B) hsp-6p::GFP reporter worms were crossed to tissue-specific cco-1 hairpin lines. Control hsp-6p::GFP shows only background GFP (i). Neuron-specific cco-1 hairpin results in upregulation of hsp-6p::GFP in the intestine (rab-3 (ii) and unc-119 (iii) lines shown). Intestine-specific ges-1p::cco-1 hairpin (iv) also results in upregulation of the hsp-6p::GFP reporter in the intestine.

(C) Fluorescent quantification of B; error bars represent standard deviation (SD).

(D) Intestinal knockdown of ubi-5 does not block UPR<sup>mt</sup> induction caused by neuronal cco-1 reduction. Worm strains were created with rab-3::cco-1HP; hsp-6p::gfp with gly-19p::ubi-5KD.

(E) Intestinal reduction of ubi-5 does not block the life-span extensions of rab-3::cco-1HP animals. sid-1(q39) (blue line, mean = 19.4 ± 0.6 days); sid-1(q39); gly-19p::ubi-5KD (red line, mean = 20.1 ± 0.7 days); rab-3::cco-1HP; gly-19p::ubi-5KD (yellow line, mean = 24.1 ± 0.7 days); rab-3::cco-1HP (green line, mean = 24.5 ± 0.7 days); N2 on cco-1 RNAi (mean = 27.3 ± 0.6 days, p > 0.66 (green versus yellow)).

(F) Intestinal reduction of ubi-5 (gly-19p::ubi-5HP) blocks UPR<sup>mt</sup> induction of animals fed bacteria expressing cco-1 dsRNA. See also Figure S4.
are required to respond to the cell-non-autonomous signals from the nervous system to induce the UPR\textsuperscript{mt}.

## DISCUSSION

This work identified key tissues, genes essential and specific for mitochondrial longevity and at least one mechanism necessary for increased longevity in response to altered mitochondrial function in a metazoan. The UPR\textsuperscript{mt} was essential for the extended longevity of ETC mutant animals and has been previously reported to be upregulated in response to RNAi of cco-1 (Yoneda et al., 2004). Consistent with the temporal requirements of the ETC to modulate longevity during the L3/L4 larval stages, the UPR\textsuperscript{mt} could only be induced when cco-1 RNAi was administered before the L3/L4 larval stage, but not in adulthood. Therefore, induction of the UPR\textsuperscript{mt} mirrored the temporal requirements of the ETC to promote longevity when reduced. More importantly, the fact that induction of the UPR\textsuperscript{mt} can be maintained long into adulthood, well after the mitochondrial insult had been given in larval development, indicates that the animal might possess an epigenetic mechanism to ensure increased resistance to future mitochondrial perturbations.

One of the most surprising findings is the UPR\textsuperscript{mt} can be activated in a cell-non-autonomous manner. Because the hsp-6p::GFP reporter is primarily limited to expression in the intestine, we were well poised to ask if perturbation of cco-1 in the nervous system could induce the UPR\textsuperscript{mt} in the intestine. Therefore, neuronal limited knockdown of cco-1 could profoundly induce the hsp-6p reporter indicates that a cue from the nervous system must travel to the intestine to induce the UPR\textsuperscript{mt} (Figure 7). It is not clear whether the factor is proteinaceous, nucleic acid based or a small molecule, but it is clear that its production in a limited number of cells can profoundly influence the survival of the entire organism. Because this signal is the product of perceived mitochondrial stress that results in increased survival, we have termed this cell-non-autonomous signal a “mitokine.”

While many of these perturbations have pleiotropic effects that result in their short life span, their ability to upregulate the UPR\textsuperscript{mt} is insufficient to overcome these potentially harmful side effects. We found that muscle-specific cco-1 RNAi could also induce the intestinal hsp-6p::GFP reporter, yet these animals were not long lived (Figure S4B). We also find that short-lived mev-1 mutant animals also induce the UPR\textsuperscript{mt} (data not shown). Finally, many of the nuclear-encoded mitochondrial genes discovered to induce the UPR\textsuperscript{mt} when inactivated using RNAi (Yoneda et al., 2004) are not long lived (data not shown). Therefore, ectopic induction of the UPR\textsuperscript{mt} is required but is not sufficient in the establishment of the longevity cue from mitochondria in these settings.

Of the currently identified UPR\textsuperscript{mt} pathway members, the ubiquitin like protein, UBL-5, which provides transcriptional specificity for the homeobox transcription factor DVE-1 in response to unfolded proteins in the mitochondria, is essential for the increased longevity of ETC mutant animals. Knockdown of ubl-5 specifically in the intestine was not sufficient to block mitokine signaling from the nervous system, but was able to block induction of animals fed dsRNA of cco-1, which can not reduce cco-1 in the nervous system. Therefore, it appears that ubl-5 either functions exclusively in a cell-autonomous fashion, or the signals generated to induce the UPR\textsuperscript{mt} in the nervous system are very different from the signal generated in other tissues as ubl-5 was not required for neuronal induction.

It is intriguing to speculate why reduced mitochondrial ETC in only a few tissues are able to send a prolongevity cue, or mitokine, but others do not. Because the intestine and the sensory neurons (amphids and phasmids) are the only cells that are in direct contact with the worm’s environment (the hypodermskin is wrapped in a protective, dense cuticle), perhaps these cells are fine-tuned to perceive mitochondrial insults that might be present in the environment. Alternatively, mitochondrial metabolism in the nervous system and intestine might have different requirements than other tissues making disruptions in these tissues more susceptible to perturbation and subsequent UPR\textsuperscript{mt} upregulation. As another possibility, there is a growing body of research emphasizing the importance of ROS, not as damaging agents, but as crucial components of cell signaling. It remains a possibility that ROS may act as signaling molecules and potentially serve as the mitokine or intermediary to elicit a nuclear response. However, animals treated with high doses of the antioxidants N-acetyl-L-cysteine (NAC) or ascorbic acid (vitamin C) were not able to block mitokine signaling (Figure S5), a thorough investigation of mitochondrial function from each tissue will be essential to test these hypotheses.

In the future it will be important to understand how mitochondrial stress initiates the UPR\textsuperscript{mt} in a cell-autonomous fashion and how this stress is then transmitted throughout the organism to...
induce the UPR\textsuperscript{mt} in cells that have yet to possess mitochondrial stress (i.e., a cell-non-autonomous fashion). Furthermore, the identity and mode of action of the mitokine will provide an avenue to explore treatment of mitochondrial diseases in a tissue and cell-type-specific manner if conserved from worm to man.

**EXPERIMENTAL PROCEDURES**

**Strains**

HCC114 (sid-1(fzg19)), MQ878 (tap-1(pm150)), CBA876 (che-1(e2519)), CF1041 (daf-2(e137)), TK22 (mev-1(kn1)III), WB27 (rde-1(ne219)), NR222 (rde-1(ne219); kis-8, NR350 (rde-1(ne219); V; kis-20), SJ4100 (zct138(hsp-6pc:GFP), SJ4058 (zct138(hsp-60c:GFP), CL2070 (dvt1(hsp-16.2::GFP)) and N2 wild-type were obtained from the Caenorhabditis Genetics Center. VP303 was a generous gift from the Strange lab.

The *myo-3* promoter hairpin RNAi transgene was created by inserting PCR amplified cco-1 cDNA with no stop codon into pPD97.86 (Addgene). The reverse complement cco-1 cDNA was inserted into pGEX2T after the GST linker to be used as the hairpin loop as described. PCR amplifications were used to add an Agel site to the 3' end of the cco-1 cDNA and NcoMV (compatible and nonreducible with Agel) to the 5' end of the GST linker. Ligation of the PCR products in the presence of Agel enzyme and NcoMV were followed by gel extraction of the promoter hairpin fragment as described (Hobert 2002). The ges-1 and unc-119 promoters were PCR amplified from genomic DNA and cloned in place of the *myo-3* promoter driving cco-1. The rab-3 promoter was a gift from Kang Shen, Stanford University, and sequence verified.

Transgenic tissue-specific RNAi hairpin expressing strains were generated by microinjecting gel extracted hairpin RNAi constructs (40-60ng/\(\mu\)l) mixed with an equal concentration of pRF4(rol-6) co-injection marker or *myo-2::GFP* into sid-1(q59) worms. Control lines were generated by injecting *sid-1(q97)* with 50ng/\(\mu\)l pRF4(rol-6). Extrachromosomal arrays were integrated and backcrossed five times as described.

The *gly-19* intestinal promoter driving wild-type *sid-1* was injected into *rab-3p::cco-1::HPL* transgenic worms to enable knockdown of *cco-1* in the neurons by the hairpin transgene and in the intestine by feeding RNAi.

*ubb-5* knockdown strains were generated with constructs as described (Esposito et al.; 2007; Hobert, 2002). Forward and reverse orientation *ubb-5* constructs were driven by the *gly-19* intestinal promoter and co-injected with the *myo-3p::tdTomato marker.

**Life-Span Analyses**

Life-span analyses were performed as described previously (Dillin et al.; 2002a). 80-100 animals were used per condition and scored every day or every other day. All life-span analyses were conducted at 20°C and repeated at least twice. JMP IN 8 software was used for statistical analysis. In all cases, \(P\)-values were calculated using the log-rank (Mantel-Cox) method.

**GFP Expression and Quantification**

SJ4100 hsp-6::GFP were bleached to collect synchronous eggs and grown on cco-1 RNAi. At each stage from larval stage 1 to Day 1 of adulthood, worms were assayed for GFP expression. Alternatively, SJ4100 worms were grown on empty vector and transferred to cco-1 RNAi at each developmental stage at which time GFP was assayed at Day 1 or 2 of adulthood.

Integrated hairpin RNAi worm lines were crossed to SJ4100 hsp-6::GFP reporter lines. GFP was monitored in Day 1 adults. Fluorometry assays were performed using a Tecxan fluorescence plate reader. 100 roller worms were picked at random (25 into 4 wells of a black walled 96-well plate) and each well was read three times and averaged. Each experiment was repeated three times.

**SUPPLEMENTAL INFORMATION**

Supplemental Information includes Extended Experimental Procedures, five figures, four tables, and one movie and can be found with this table online at doi:10.1016/j.cell.2010.12.016.
